

Joshimath Landslide Susceptibility

Random Forest with spatial cross-validation: terrain/optical predictors vs. terrain/optical + InSAR velocity

Main result

Without InSAR: AUROC 0.872, F1 0.828

With InSAR: AUROC 0.893, F1 0.857

InSAR improved both metrics in the common valid-coverage experiment.

Interpretation

High susceptibility concentrates on steep, dissected valley-side terrain; velocity adds a deformation signal.

Caveat

Only 14 landslide samples overlap valid InSAR coverage, so the improvement is promising but preliminary.
